

The learned camera-model residual — 7 myscenes scenes, ONE physical lens, seven independent COLMAP fits — in ANGLE, never in pixels.
The spline is parameterised on $\theta/(\pi/2)$, so it is defined out to 90° on every scene; only $\theta \leq 85.5^\circ$ is ever evaluated, and everything past the dotted line is extrapolation the loss never saw.

A. radial channel $k=0$ of the learned $\Delta\theta$

B. anamorphic channels $k=1,2$ (RMS over the four harmonics)

C. the non-central profile $z(\theta)$
